How to synchronize a network update on N9 in QML

This article explains how to trigger a job, usually a network update, that is synchronized with other network activity.

04 Dec 2011

Introduction

This short article gives an example of the AlignedTimer QML object from the Qt Mobility 1.2 API. This component allows the creation of a timer that will be triggered at the same time as other applications' timers. This is useful to synchronize updates, for example to group network updates together (reduce power consumption on mobile devices).

Summary

The following code shows an example of AlignedTimer. This timer will be triggered between 15 and 30 minutes later, based on other applications' use of AlignedTimers. The system will try to synchronize them as much as possible, to reduce the number of wake-ups, or number of times the network needs to be brought up.

```
import QtQuick 1.0
import com.nokia.meego 1.0
import QtMobility.systeminfo 1.2

PageStackWindow {
    id: window
[...]
    // Create the AlignedTimer
    AlignedTimer {
        id: alignedTimer
        // Set the timer to trigger between 15 and 30 minutes
        // Other applications using an AlignedTimer would be triggered
        //  during this same interval (for example mail sync) if possible
        maximumInterval: 30*60   // in seconds
        minimumInterval: 15*60    // in seconds
        singleShot: true  // Run it only once. Comment this line for a recurring timer
        onTimeout: {
            // Place update code, such as network sync here
        }
    }

    Component.onCompleted: {
        // Start the time once the PageStackWindow is created (application loaded)
        alignedTimer.start()
    }
[...]
```
